# Natural Language Processing

**BITS Pilani**  
Pilani Campus

Dr. Chetana Gavankar, Ph.D,  
IIT Bombay-Monash University Australia  
[Chetana.gavankar@pilani.bits-pilani.ac.in](mailto:Chetana.gavankar@pilani.bits-pilani.ac.in)

## Session 4

These slides are prepared by the instructor, with grateful acknowledgement of Jurafsky and Martin and many others who made their course materials freely available online.

# Session Content

---

- Language Models
- Real world applications of language modelling
- How to build language models
- Evaluation of Language models
- Perplexity
- Smoothing, Interpolation and Back off

# Language modelling

A model that computes either of these:

Probability of a sentence (  $P(W)$  ) or

Probability of an upcoming word (  $P(w_n | w_1, w_2 \dots w_{n-1})$  )  
is called a **language model**.

Simply we can say that

A language model learns to predict the probability of a sequence of words.

# Example

# Language Models

Machine Translation

## 1. Machine Translation:

Machine translation system is used to translate one language to another language

$P(\text{high winds tonight}) > P(\text{large winds tonight})$

## 2. Spell correction

The office is about fifteen minuets from my house

$P(\text{about fifteen } \mathbf{minutes} \text{ from}) > P(\text{about fifteen } \mathbf{minuets} \text{ from})$

## 3.Speech Recognition

---

**Speech recognition** is the ability of a machine or program to identify words and phrases in spoken language and convert them to a machine-readable format.

Example:

$P(\text{I saw a van}) \gg P(\text{eyes awe of an})$

# How to build a language model

- Recall the definition of conditional probabilities

$$p(B|A) = P(A,B)/P(A) \quad \text{Rewriting: } P(A,B) = P(A)P(B|A)$$

- More variables:

$$P(A,B,C,D) = P(A)P(B|A)P(C|A,B)P(D|A,B,C)$$

- The **Chain Rule** in General

$$P(x_1, x_2, x_3, \dots, x_n) = P(x_1)P(x_2|x_1)P(x_3|x_1, x_2) \dots P(x_n|x_{n-1}, x_{n-2}, \dots, x_1)$$

# The Chain Rule applied to compute joint probability of words in sentence

$$P(w_1 w_2 \dots w_n) = \prod_{k=1}^n P(w_k | w_1^{k-1})$$

For ex:

$P(\text{"its water is so transparent"}) =$

$P(\text{its}) \times P(\text{water} | \text{its}) \times P(\text{is} | \text{its water})$

$\times P(\text{so} | \text{its water is}) \times P(\text{transparent} | \text{its water is so})$

Where:

$P(\text{its}) = \#(\text{its})$

$P(\text{water} | \text{its}) = \#(\text{its water}) / \#(\text{its})$

$P(\text{is} | \text{its water}) = \#(\text{its water is}) / \#(\text{its water})$

$P(\text{so} | \text{its water is}) = \#(\text{its water is so}) / \#(\text{its water is})$

$P(\text{the} | \text{its water is so transparent}) = \#(\text{its water is so transparent}) / \#(\text{its water is so})$

# Markov Assumption

- Simplifying assumption:

*limit history of fixed number of words,  $n$*

Andrei Markov

$P(\text{the} \mid \text{its water is so transparent that}) \gg P(\text{the} \mid \text{that})$

or

$P(\text{the} \mid \text{its water is so transparent that}) \gg P(\text{the} \mid \text{transparent that})$

# Markov Assumption

---

$$P(w_1 w_2 \dots w_n) \approx \prod_i P(w_i \mid w_{i-k} \dots w_{i-1})$$

In other words, we approximate each component in the product

$$P(w_i \mid w_1 w_2 \dots w_{i-1}) \approx P(w_i \mid w_{i-k} \dots w_{i-1})$$

# N-gram Language models

---

- N gram is a sequence of tokens(words)
- Unigram language model(N=1 )

$$P(w_1 w_2 \dots w_n) \approx \prod_i P(w_i)$$

Example:

**$P(\text{I want to eat healthy food}) \approx P(\text{I})P(\text{want})$   
 $P(\text{to})P(\text{eat})P(\text{healthy})P(\text{food})$**

# Bigram model

N=2

$$P(w_i | w_1 w_2 \dots w_{i-1}) \approx P(w_i | w_{i-1})$$

Example:

$P(\text{I want to eat healthy food}) \approx P(\text{I} | \text{<start>}) P(\text{want} | \text{I}) P(\text{to} | \text{want})$   
 $P(\text{eat} | \text{to}) P(\text{healthy} | \text{eat}) P(\text{food} | \text{healthy})$   
 $P(\text{<end>} | \text{food})$

# N-gram models

---

- We can extend to trigrams, 4-grams, 5-grams
- In general this is an insufficient model of language
  - because language has **long-distance dependencies**:  
“The computer(s) which I had just put into the machine room on the fifth floor is (are) crashing.”

# Estimating bigram probabilities

---

- The Maximum Likelihood Estimate

$$P(w_i | w_{i-1}) = \frac{\textit{count}(w_{i-1}, w_i)}{\textit{count}(w_{i-1})}$$

$$P(w_i | w_{i-1}) = \frac{c(w_{i-1}, w_i)}{c(w_{i-1})}$$

# An example

$$P(w_i | w_{i-1}) = \frac{c(w_{i-1}, w_i)}{c(w_{i-1})}$$

<s> I am Sam </s>

<s> Sam I am </s>

<s> I do not like green eggs and ham </s>

$$P(\text{I} | \text{<s>}) = \frac{2}{3} = .67$$

$$P(\text{Sam} | \text{<s>}) = \frac{1}{3} = .33$$

$$P(\text{am} | \text{I}) = \frac{2}{3} = .67$$

$$P(\text{</s>} | \text{Sam}) = \frac{1}{2} = 0.5$$

$$P(\text{Sam} | \text{am}) = \frac{1}{2} = .5$$

$$P(\text{do} | \text{I}) = \frac{1}{3} = .33$$

# More examples:

## Berkeley Restaurant Project sentences

---

- can you tell me about any good cantonese restaurants close by
- mid priced thai food is what i'm looking for
- tell me about chez panisse
- can you give me a listing of the kinds of food that are available
- i'm looking for a good place to eat breakfast
- when is caffe venezia open during the day

# Raw bigram counts

- Out of 9222 sentences

|         | i  | want | to  | eat | chinese | food | lunch | spend |
|---------|----|------|-----|-----|---------|------|-------|-------|
| i       | 5  | 827  | 0   | 9   | 0       | 0    | 0     | 2     |

| 2533 | 927  | 2417 | 746 | 158     | 1093 | 341   | 278   |

$$P((i|i)=5/2533=0.002$$

$$P(\text{want}|i)= 827 / 2533 = 0.33$$

$$P(\text{to}|i) = 0 / 2533 = 0$$

$$P(\text{eat}|i)= 9 / 2533 = 0.0036$$

$$P(i|\text{want})=2/927=0.0022$$

$$P(\text{to}|\text{want}) = 608 / 927=0.66$$

$$P(\text{eat}|\text{to}) = 686/2417 = 0.28$$

|         | i       | want | to     | eat    | chinese | food   | lunch  | spend   |
|---------|---------|------|--------|--------|---------|--------|--------|---------|
| i       | 0.002   | 0.33 | 0      | 0.0036 | 0       | 0      | 0      | 0.00079 |
| want    | 0.0022  | 0    | 0.66   | 0.0011 | 0.0065  | 0.0065 | 0.0054 | 0.0011  |
| to      | 0.00083 | 0    | 0.0017 | 0.28   | 0.00083 | 0      | 0.0025 | 0.087   |
| eat     | 0       | 0    | 0.0027 | 0      | 0.021   | 0.0027 | 0.056  | 0       |
| chinese | 0.0063  | 0    | 0      | 0      | 0       | 0.52   | 0.0063 | 0       |
| food    | 0.014   | 0    | 0.014  | 0      | 0.00092 | 0.0037 | 0      | 0       |
| lunch   | 0.0059  | 0    | 0      | 0      | 0       | 0.0029 | 0      | 0       |
| spend   | 0.0036  | 0    | 0.0036 | 0      | 0       | 0      | 0      | 0       |

# Bigram estimates of sentence probabilities

$$\begin{aligned} P(<s> \text{ I want english food } </s>) &= \\ &P(\text{I} | <s>) \\ &\times P(\text{want} | \text{I}) \\ &\times P(\text{english} | \text{want}) \\ &\times P(\text{food} | \text{english}) \\ &\times P(</s> | \text{food}) \\ &= .000031 \end{aligned}$$

# What kinds of knowledge?

---

- $P(\text{english} | \text{want}) = .0011$
- $P(\text{chinese} | \text{want}) = .0065$
- $P(\text{to} | \text{want}) = .66$
- $P(\text{eat} | \text{to}) = .28$
- $P(\text{food} | \text{to}) = 0$
- $P(\text{want} | \text{spend}) = 0$
- $P(i | \langle s \rangle) = .25$

# Practical Issues

---

- We do everything in log space
  - Avoid underflow
  - (also adding is faster than multiplying)

$$\log(p_1 \cdot p_2 \cdot p_3 \cdot p_4) = \log p_1 + \log p_2 + \log p_3 + \log p_4$$

## All Our N-gram are Belong to You

Posted by Alex Franz and Thorsten Brants, Google Machine Translation Team

Here at Google Research we have been using word [n-gram models](#) for a variety of R&D projects,

...

That's why we decided to share this enormous dataset with everyone. We processed 1,024,908,267,229 words of running text and are publishing the counts for all 1,176,470,663 five-word sequences that appear at least 40 times. There are 13,588,391 unique words, after discarding words that appear less than 200 times.

# Google N-Gram Release

---

- serve as the incoming 92
- serve as the incubator 99
- serve as the independent 794
- serve as the index 223
- serve as the indication 72
- serve as the indicator 120
- serve as the indicators 45
- serve as the indispensable 111
- serve as the indispensable 40
- serve as the individual 234

<https://pypi.org/project/google-ngram-downloader/>

# The perils of overfitting

---

- N-grams only work well for word prediction if the test corpus looks like the training corpus
  - In real life, it often doesn't
  - We need to train robust models that generalize!
  - One kind of generalization: Zeros!
    - Things that don't ever occur in the training set
      - But occur in the test set

# Zeros

---

- Training set:
  - ... denied the allegations
  - ... denied the reports
  - ... denied the claims
  - ... denied the request
- Test set
  - ... denied the offer
  - ... denied the loan

$$P(\text{"offer"} \mid \text{denied the}) = 0$$

# Zero probability bigrams

---

- Bigrams with zero probability
  - mean that we will assign 0 probability to the test set!

# Laplace Smoothing(Add 1 smoothing)

- Pretend we saw each word one more time than we did
- Just add one to all the counts!

- MLE estimate:

$$P_{MLE}(w_i | w_{i-1}) = \frac{c(w_{i-1}, w_i)}{c(w_{i-1})}$$

- Add-1 estimate:

$$P_{Add-1}(w_i | w_{i-1}) = \frac{c(w_{i-1}, w_i) + 1}{c(w_{i-1}) + V}$$

# Maximum Likelihood Estimates

---

- The maximum likelihood estimate
  - of some parameter of a model  $M$  from a training set  $T$
  - maximizes the likelihood of the training set  $T$  given the model  $M$
- Suppose the word “bagel” occurs 400 times in a corpus of a million words
- What is the probability that a random word from some other text will be “bagel”?
- MLE estimate is  $400/1,000,000 = .0004$
- This may be a bad estimate for some other corpus
  - But it is the **estimate** that makes it **most likely** that “bagel” will occur 400 times in a million word corpus.

# Add-1 estimation is a blunt instrument

---

- So add-1 isn't used for N-grams:
  - We'll see better methods
- But add-1 is used to smooth other NLP models
  - For text classification
  - In domains where the number of zeros isn't so huge.

# Backoff and Interpolation

---

- Sometimes it helps to use **less** context
  - Condition on less context for contexts you haven't learned much about
- **Backoff:**
  - use trigram if you have good evidence,
  - otherwise bigram, otherwise unigram
- **Interpolation:**
  - mix unigram, bigram, trigram
- Interpolation works better

# Linear Interpolation

- Simple interpolation

$$\begin{aligned}\hat{P}(w_n|w_{n-2}w_{n-1}) = & \lambda_1 P(w_n|w_{n-2}w_{n-1}) \\ & + \lambda_2 P(w_n|w_{n-1}) \\ & + \lambda_3 P(w_n)\end{aligned}\quad \sum_i \lambda_i = 1$$

- Lambdas conditional on context:

$$\begin{aligned}\hat{P}(w_n|w_{n-2}w_{n-1}) = & \lambda_1(w_{n-2}^{n-1})P(w_n|w_{n-2}w_{n-1}) \\ & + \lambda_2(w_{n-1}^{n-1})P(w_n|w_{n-1}) \\ & + \lambda_3(w_{n-2}^{n-1})P(w_n)\end{aligned}$$

# How to set the lambdas?

- Use a **held-out** corpus

- Choose  $\lambda$ s to maximize the probability of held-out data:
  - Fix the N-gram probabilities (on the training data)
  - Then search for  $\lambda$ s that give largest probability to held-out set:

$$\log P(w_1 \dots w_n \mid M(I_1 \dots I_k)) = \sum_i \log P_{M(I_1 \dots I_k)}(w_i \mid w_{i-1})$$

# Unknown words: Open versus closed vocabulary tasks

- If we know all the words in advanced
  - Vocabulary  $V$  is fixed
  - Closed vocabulary task
- Often we don't know this
  - **Out Of Vocabulary** = OOV words
  - Open vocabulary task
- Instead: create an unknown word token <UNK>
  - Training of <UNK> probabilities
    - Create a fixed lexicon  $L$  of size  $V$
    - At text normalization phase, any training word not in  $L$  changed to <UNK>
    - Now we train its probabilities like a normal word
  - At decoding time
    - If text input: Use UNK probabilities for any word not in training

# Huge web-scale n-grams

---

- How to deal with, e.g., Google N-gram corpus
- Pruning
  - Only store N-grams with count  $>$  threshold.
    - Remove singletons of higher-order n-grams

# Smoothing for Web-scale N-grams

- “Stupid backoff” (Brants *et al.* 2007)
- No discounting, just use relative frequencies

$$S(w_i | w_{i-k+1}^{i-1}) = \begin{cases} \frac{\text{count}(w_{i-k+1}^i)}{\text{count}(w_{i-k+1}^{i-1})} & \text{if } \text{count}(w_{i-k+1}^i) > 0 \\ 0.4S(w_i | w_{i-k+2}^{i-1}) & \text{otherwise} \end{cases}$$

$$S(w_i) = \frac{\text{count}(w_i)}{N}$$

# Evaluation: How good is our model?

- Does our language model prefer good sentences to bad ones?
  - Assign higher probability to “real” or “frequently observed” sentences
    - Than “ungrammatical” or “rarely observed” sentences?
- We train parameters of our model on a **training set**.
- We test the model’s performance on data we haven’t seen.
  - A **test set** is an unseen dataset that is different from our training set, totally unused.
  - An **evaluation metric** tells us how well our model does on the test set.

# Experimental setup

# Extrinsic evaluation of N-gram models

- Best evaluation for comparing models A and B
  - Put each model in a task
    - spelling corrector, speech recognizer, MT system
  - Run the task, get an accuracy for A and for B
    - How many misspelled words corrected properly
    - How many words translated correctly
  - Compare accuracy for A and B

# Difficulty of extrinsic (in-vivo) evaluation of N-gram models

- Extrinsic evaluation
  - Time-consuming; can take days or weeks
- So
  - Sometimes use **intrinsic** evaluation: **perplexity**
  - Bad approximation
    - unless the test data looks **just** like the training data
    - So **generally only useful in pilot experiments**
  - But is helpful to think about.

# Intuition of Perplexity

- The Shannon Game:
  - How well can we predict the next word?

I always order pizza with cheese and \_\_\_\_\_

The 33<sup>rd</sup> President of the US was \_\_\_\_\_

I saw a \_\_\_\_\_

mushrooms 0.1

pepperoni 0.1

anchovies 0.01

....

fried rice 0.0001

....

and 1e-100

- Unigrams are terrible at this game. (Why?)
- A better model of a text
  - is one which assigns a higher probability to the word that actually occurs

# Why Perplexity

- **Longer sentences always have smaller probabilities**
- Sentence probability is computed as:
- $P(w_1 w_2 \dots w_n) = \prod_{k=1}^n P(w_k | w_1^{k-1})$
- Multiplying many probabilities (each  $< 1$ ) gives a **very tiny number**.
- A **longer sentence** will always have a smaller probability than a short sentence — even if the model is good.

**So comparing raw probabilities is meaningless.**

- Example:
  - Model A:  
 $P(\text{"I like cats"}) = 0.01$   
 $P(\text{"I like cute cats very much"}) = 0.00003$
  - Does this mean model A is bad?  
No — the second sentence is just longer.

# Why Perplexity

- Two models might give:
  - Model A: probability = 0.0001
  - Model B: probability = 0.0000000002
- If the sentences are different lengths, **you can't compare them directly.**
- We need a **length-normalized score.**
- It converts the probability of the whole sentence into an **average per-word confusion measure:**

$$\begin{aligned} PP(W) &= P(w_1 w_2 \dots w_N)^{-\frac{1}{N}} \\ &= \sqrt[N]{\frac{1}{P(w_1 w_2 \dots w_N)}} \end{aligned}$$

- This is the **geometric mean of inverse probabilities.**  
**Minimizing perplexity is the same as maximizing probability**

# Why Perplexity

- **Length Normalized**

Perplexity makes models **comparable even if sentences differ in length.**

It answers:

“On average, how many choices does the model seem confused between per word?”

- **Easy to interpret**

If perplexity = **10**,

→ The model is as uncertain as choosing from **10 equally likely words.**

If perplexity = **2**,

→ Very confident (like flipping a coin).

If perplexity = **100**,

→ Very confused.

This interpretation is **much clearer** than reading probabilities like 0.00000003265

# Why Perplexity

---

- **Allows fair model comparison**

Two LMs can be compared fairly

Language modeling benchmarks use PPL for standardized evaluation

Perplexity works across n-grams, RNNs, LSTMs, transformers

- **Stable and robust metric**

Probabilities shrink exponentially.

Perplexity stays within a **reasonable numeric range** (e.g., 10–400), making comparison easy

# Example

Sentence: “**I love NLP models**”

Number of words: **N = 4**

Suppose a language model gives the following probabilities:

**Compute total sentence probability**

$$P = 0.10 \times 0.20 \times 0.25 \times 0.50$$

$$P = 0.0025$$

| Word   | Probability |
|--------|-------------|
| I      | 0.10        |
| love   | 0.20        |
| NLP    | 0.25        |
| models | 0.50        |

**Apply the perplexity formula:**  $PP(W) = P(w_1 w_2 \dots w_N)^{-\frac{1}{N}}$

$$N=4$$

$$PPL = (0.0025)^{-1/4}$$

$$PPL = (1/400)^{-1/4} \approx 4.47$$

$$= \sqrt[4]{\frac{1}{P(w_1 w_2 \dots w_N)}}$$

Model is as uncertain as choosing between **about 5 equally likely words** at each position.  
Lower perplexity = better language model.

# Perplexity as branching factor

---

- Let's suppose a sentence consisting of random digits 0 to 9 Ex: 0,2,1,3.....N
- What is the perplexity of this sentence according to a model that assign  $P=1/10$  to each digit?

$$\begin{aligned} \text{PP}(W) &= P(w_1 w_2 \dots w_N)^{-\frac{1}{N}} \\ &= \left(\frac{1}{10}\right)^{-\frac{1}{N}} \\ &= \frac{1}{10}^{-1} \\ &= 10 \end{aligned}$$

# Lower perplexity = better model

---

- Training 38 million words, test 1.5 million words, WSJ

| N-gram<br>Order | Unigram | Bigram | Trigram |
|-----------------|---------|--------|---------|
| Perplexity      | 962     | 170    | 109     |

# Corpora of text and speech

- Brown Corpus
- Wall Street Journal
- AP newswire
- Hansards
- DARPA/NIST text/speech corpora (Call Home, ATIS, switchboard, Broadcast News, TDT, Communicator)
- TRAINS, Radio News

# N-gram versus LLM(neural language models)

| Feature                      | N-gram Models                      | LLMs                  |
|------------------------------|------------------------------------|-----------------------|
| <b>Training Data Needed</b>  | Very small                         | Huge                  |
| <b>Compute</b>               | Low                                | Very high             |
| <b>Interpretability</b>      | Excellent                          | Poor                  |
| <b>Handles Long Context?</b> | No                                 | Yes                   |
| <b>Quality of Language?</b>  | Low–medium                         | Very high             |
| <b>Hallucination</b>         | Almost none                        | Possible              |
| <b>Deployment</b>            | Easy, lightweight                  | Heavy, expensive      |
| <b>Use Cases</b>             | Small, fast, interpretable systems | Large-scale NLP tasks |
